US PAT NO: 5,750,105 [IMAGE AVAILABLE] L2: 1 of 3

CLAIMS:

CLMS(8)

8. The method of claim 1, wherein the treatment comprises treatment of a disease selected from the group consisting of rheumatoid **arthritis**, eczema, and immuno-modulated diseases, and the antigen bound by the **antibody** is **CD4**.

US PAT NO: 5,741,488 [IMAGE AVAILABLE] L2: 2 of 3

CLAIMS:

CLMS(1)

We claim:

1. A method of treating rheumatoid **arthritis** in a mammal comprising administering to said mammal a therapeutically effective amount of anti-**CD4 antibody** and anti-TNF **antibody**.

US PAT NO: 4,695,459 [IMAGE AVAILABLE] L2: 3 of 3

CLAIMS:

CLMS(1)

We claim:

1. A method of treating a patient for an **autoimmune** disease that is mediated by Leu3(**CD4**) phenotype T cells comprising parenterally administering a therapeutically effective amount of an anti-Leu3(**CD4**) **antibody** that binds to said T cells to the patient.

Inhibitory anti-**antibodies** induced in patients by xenogeneic or even by **humanized** anti-T cell **antibodies** remain an unresolved problem. Mice also produce anti-**antibodies** following injection of xeno- or allogeneic anti-T cell **antibodies** . Here we report a principle based on sequentially applied anti-T cell **antibodies** generated in different species, which results in suppressed anti-**antibody** formation and prolonged immunosuppression. Thus, a single priming injection in mice of mouse (MmT1 or MmT5 differing by idiotype only) or of rat (RmT1) anti-mouse Thy-1 monoclonal **antibodies** (mAb) or of rat anti-mouse L3T4 + Ly-2 (RmCD4 + **CD8**) mAb suppressed anti-**antibody** formation against subsequent booster injections of one of the above **antibodies**, provided that they differed in species origin from the priming **antibody** . Correspondingly, a sixfold and longer prolongation of 50 % survival of fully mismatched skin grafts was observed. Less or no anti-**antibody** suppression and little prolongation of graft survival was obtained if the 'first' and the 'second' (and following) **antibody** injections were of the same species, differing by iso- or idiotype only. Finally, the suppressive principle did not manifest itself at all if the initial **antibody** injection included both the first and second **antibody** . These findings are discussed with reference to earlier studies on hapten/carrier effects as well as on immunosuppression attributed to **'non-depleting'** rat anti-CD4/**CD8** T cell **antibodies**.

In the current study, we investigated the presence of a cross-reactive antigen(s) in the erythrocyte stage from Plasmodium yoelii (265 BY strain) and Plasmodium falciparum through recognition by T cells primed in vivo with antigens from each of these parasites. BALB/c mice are naturally resistant to P. falciparum but are susceptible to P. yoelii infection. Mice that had recovered from P. yoelii primary infection became resistant to a second infection. A higher in vitro proliferative response to a soluble blood stage preparation of P. falciparum was observed in splenic cells from immune animals than in those from mice with a patent P. yoelii infection. The antigen-induced proliferative response was enhanced when animals were exposed to a secondary infection. Animals exposed to a challenge infection were treated with anti-CD4 or anti-**CD8** monoclonal **antibodies** to deplete the corresponding subset of T cells. There was a marked diminution in P. falciparum antigen-induced proliferative response in the total splenic cell populations from **CD8**-depleted but not from CD4-depleted mice. In **CD8**-depleted and **nondepleted** animals, the antigen-induced proliferation in the total cell populations was markedly lower than in the T-cell-rich populations, indicating inhibitory activities of B cells and/or macrophages. There was no such difference in the stimulation between total and T-enriched cell populations from CD4-depleted

animals. Flow cytometry analysis demonstrated the presence of an almost equal percentage of **CD8**+ (59.6%) and CD4+ (64%) T cells in the spleen preparations following in vivo depletion of CD4- and **CD8**-bearing T cells, respectively. When cultured with P. yoelii blood stage antigen, splenocytes from animals immunized with P. falciparum antigen displayed a significant proliferative response which was markedly diminished by treatment with anti-Thy-1.2 **antibody** plus complement. Animals immunized with P. falciparum antigen and then challenged with P. yoelii blood stage parasites displayed about a 50% lower level of parasitemia. These results demonstrated the existence of a cross-reactive antigen(s) between a murine and a **human** Plasmodium species, as determined from both in vivo and in vitro biological assays, and indicated the reactivity of mainly **CD8**+ T cells with this antigen.

Full Journal Title: Blood
Language: ENGLISH
After marrow transplantation, major histocompatibility complex (MHC)-unrestricted natural killer (NK) lymphocytes are among the first cells to appear in the circulation. After T-cell-depleted bone marrow transplantation (TD-BMT), these cells have an activated pattern of target cell killing; they also secrete lymphokines including .gamma.-interferon (.gamma.-IFN), interluekin-2 (IL-2), and tumor necrosis factor (TNF) and may have a significant role as a primary defense against viral reactivation and in the elimination of residual host malignancy. We studied 43 patients with hematologic malignancy, treated by allogeneic TD-BMT, autologous **nondepleted** BMT, or chemotherapy alone to investigate (a) the mechanisms underlying the generation of these activated killer cells, (b) the range of conditions under which they are produced, and (c) their surface phenotype. We showed that .gamma.-IFN-secreting activated killer cells with the capacity to kill MHC-nonidentical NK-resistant targets are generated 4 to 6 weeks after either allogeneic TD-BMT or autologous BMT but do not appear after treatment with chemotherapy. Production therefore is not owing to T-cell depletion per se or to host donor alloreactivity, nor is it caused by stimulation by alloantigens contained in blood product support since no significant difference exists between allograft and chemotherapy patients in the number of units of blood platelet support given in the posttreatment period. Because most patients had no evidence of stimulation from virus reactivation/infection, the phenomenon of activation therefore appears to represent posttransplant immune disregulation following repopulation of the host immune system with lymphoid subsets derived exclusively from blood and marrow. Activated killing is predominantly mediated by the CD16+ CD3- subset, but substantial activity remains in the CD16- CD3+ cell fraction. Monoclonal **antibodies** (MoAbs) that block interaction with class-I MHC molecules at the level of target cell (W6/32 anti-HLA class I) or effector cell (**CD8**) do not inhibit killing by CD16- CD3+ cells. Activated killer cells may contribute to the lower risk of relapse after marrow transplantation as compared with intensive chemotherapy.

Sixteen patients with hematological malignancy received cyclophosphamide (120 mg/kg), fractionated total body irradiation (12 Gy), oral cyclosporin, and an HLA-identical sibling marrow transplant depleted of T cells by incubation with the monoclonal **antibody** antiHuLy-m1 (CD2) and rabbit complement with (five patients) or without (11 patients) anti-HuLy-m8 (**CD8**). These 16 patients were compared historically to 84 patients with hematological malignancy receiving cyclophosphamide (120 mg/kg), fractionated total body irradiation (12 or 14 Gy), oral cyclosporin, and unmanipulated HLA-identical sibling marrow, for parameters of engraftment and graft-versus-host disease (GVHD). Graft failure occurred in one of the 16 T-cell depleted recipients and in one of the 84 **non-depleted** recipients. Engraftment was slightly but significantly slower in the T-cell depleted group and bacterial infections significantly more frequent and severe than in the unmanipulated group. There was a suggestion that the severity of acute GVHD was reduced in those receiving T depleted marrow. Randomized trials will be necessary to determine if marrow T-cell depletion results in superior long-term leukemia-free survival.

CODEN: IMRED ISSN: 0105-2896 ADONIS ORDER NUMBER: 010528969200046X
LANGUAGES: English SUMMARY LANGUAGES: English
We have described the studies from our laboratory which demonstrate that depleting anti-CD4 mAb induce tolerance to foreign antigens in adult, euthymic animals. Further, we have proposed that such tolerance occurs as a result of new thymic migrants encountering antigens in the periphery. However, these conclusions can be considered only partial since we (Song et al. in press) and others have shown that depletion of T cells per se does not permit tolerance. For example, anti-Thy-1 or anti-Lyt-1 are themselves immunosuppressive and able to deplete T cells, yet they elicit strong anti-globulin responses against themselves and do not permit tolerance to be induced either to transplants or administered soluble protein antigen. We have recently found that while the combination of anti-CD4 and anti-**CD8** mAb allows long-term survival of allografted islets in mice, anergy in the relevant T-cell subsets was not found (in contrast to what is found with anti-CD4 mAb treatment alone) (Song et al. in press). In this instance, long-term survival was probably the result of changes in graft immunogeneity (i.e., migration of passenger leukocytes) since the kinetics of repopulation were much delayed in the anti-CD4 and -**CD8** treated mice. As discussed elsewhere in this volume, interesting studies from several laboratories suggest that **non-depleting** anti-CD4 mAb can generate unresponsiveness in a variety of systems. In reviewing the literature it is clear that the success of **non-depleting** reagents appears to be dependent upon the model system tested. For example, although depleting and **nondepleting** CD4 mAb regimens produced

comparable prolongation of cultured fetal pancreas allografts in mice (Charlton and Mandel), almost total elimination of circulating CD4+ cells did not prevent acute rejection of murine skin grafts (Auchincloss et al. 1988). This heterogeneity is not surprising given the multiple functional roles of the CD4 molecule and the cells that bear this molecule. In addition to depletion, **antibodies** directed against CD4 can potentially affect CD4+ cell function by (1) direct blockade or failure to augment the formation of the TCR-antigen/MHC ternary complex or (2) by transmitting a negative signal to the CD4 T cell or interfering with normal signal transduction mechanisms. Undoubtedly, it is a combination of mechanisms that allows these **antibodies** their immunosuppressive effects. What can be said with certainty is that these **antibodies** will continue to be important tools for understanding the molecular and cellular basis of the immune response, and will soon emerge as invaluable therapeutic agents in the clinical arena.

LANGUAGES: English
There are three ways in which monoclonal **antibodies** could be used to facilitate the induction of tolerance to foreign tissues after organ transplantation. First, depleting monoclonal **antibodies** could be directed against the T cells responsible, thereby reducing their number and acting to non-specifically immunosuppress the patient. This is generally not sufficient to allow tolerance induction in the T cells which repopulate the periphery. Second, depleting monoclonal **antibodies** could be used to remove donor passenger leukocytes and antigen-presenting cells from the donor organ, which may both reduce immunogenicity and increase the chance of tolerance induction. Third, **non-depleting**, but functionally blocking, monoclonal **antibodies** to T cell molecules such as CD4 and **CD8** can allow the specific induction of transplantation tolerance in mouse models, an approach which might be applicable to man, not only for organ transplantation, but also in the treatment of autoimmune diseases. These three approaches are, in time, likely to complement each other in clinical practice. Monoclonal **antibodies** can be tailored to each approach by choosing appropriate specificities and isotypes, and further refinements can be made where necessary by making monovalent or **humanised antibodies** . The application of each of these approaches to clinical therapy is described.

LANGUAGES: English

Our goal has been to develop ways to tolerize the mature immune system to any defined antigen. In this report we show that peripheral (post-thymic) T cells of mice can become tolerant to a range of antigens (**human** and rat **immunoglobulins** , and bone marrow and skin grafts that differ at multiple minor transplantation antigens). In the case of **human** gamma globulin (HGG), this required that the antigen be given under the cover of a short course of **non-depleting** anti-CD4 **antibody**, while for tolerance to skin and marrow grafts anti-**CD8 antibody** was also required. Tolerance to HGG could be reinforced by repeated injections of HGG, but was lost in the absence of any further exposure to antigen. This reversal of tolerance with time was due to new T cells being exported from the thymus, as it was not observed in tolerized, adult thymectomized mice. In contrast, tolerance to marrow and skin grafts was permanent, presumably because the established grafts acted as a continuous source of antigen to reinforce the tolerant state. Tolerance could not be broken by the infusion of unprimed spleen cells and in one example (tolerance to Mls-1a) there was clear evidence that specific peripheral T cells were anergic. We propose that anergic cells may themselves participate in reinforcing the tolerant state by competing at sites of antigen presentation.

Languages: ENGLISH

Document type: JOURNAL ARTICLE

The presence of activated CD4(+) T lymphocytes in psoriatic skin plaques suggests an immune-mediated pathogenesis for the disease. Six patients with recalcitrant plaque psoriasis (PASI>12) received a **humanized non-depleting** monoclonal **antibody** to CD4 (ORTHOCLONE OKT(R)cdr4a). The **antibody** was well tolerated. Four weeks from treatment, the mean decrease in PASI score was 46%. In three patients disease remission was prolonged for up to 6 months and, in one case, up to 1 year post-treatment. In all patients, circulating CD4+ T-cell counts remained normal and peripheral OKTcdr4a-coated CD4+ lymphocytes were detected up to 10 days after **antibody** infusion. These results point to the relevance of CD4+ lymphocytes in psoriasis. They also emphasize that depletion of CD4+ cells is not mandatory to achieve therapeutic effectiveness.

Reprogramming the immune system for tolerance with monoclonal **antibodies**.

Cobbold SP; Qin SX; Waldmann H

Department of Pathology, Cambridge University, UK.

Semin Immunol (UNITED STATES) Nov 1990, 2 (6) p377-87, ISSN 1044-5323 Journal Code: A61

Languages: ENGLISH

Document type: JOURNAL ARTICLE; REVIEW; REVIEW, TUTORIAL

Monoclonal **antibodies** to CD4, **CD8** and CD11a can be used in vivo either to deplete or functionally block T cells to create a tolerance permissive environment. Short courses of **non-depleting** CD4 and **CD8 antibodies** were used to induce tolerance separately in CD4+ and **CD8**+ T cells either to foreign **immunoglobulins**, bone marrow, or skin grafts. Tolerance was obtained to minor (non-MHC) transplantation antigens without T cell depletion even in actively sensitized mice, or to MHC plus minor antigens presented directly by skin grafts using combinations of depleting followed by blockading CD4 and **CD8 antibodies** . In all cases, tolerance was specific to the antigen/tissue given under cover of **antibody** treatment, and in one example it could be shown that T cells directed to MLS-1a had been forced into an anergic state. This induction of tolerant, anergic T cells in the periphery is able to explain many of the features associated with tolerance, not only in the model systems using foreign antigens, but also in the normal regulation of anti-self responses and its failure in autoimmune diseases. It is our new found ability to use antigen under the cover of **antibody** treatment to accurately control the pattern of tolerant T cells in vivo that we refer to by using the term 'reprogramming'. We also describe the clinical treatment of one patient with an autoimmune vasculitis based on the ideas developed from the mouse models. (47 Refs.)

Abstract (Basic): WO 9015152 A

Non depleting CD4 and **CD8** monoclonal **antibodies** are claimed for use in inducing tolerance to an antigen. The use of these **antibodies** and packs contg. them are also claimed. The prods. may also contain a depleting CD4 monoclonal **antibody** and/or a depleting **CD8** monoclonal **antibody**.

Single dose for a **human** is 1-400mg (esp. 3-30mg) of **antibody**. Admin. is parenteral e.g. intravenous.

USE/ADVANTAGE - For producing tolerance to foreign **immunoglobulins**, bone marrow and skin grafts. To treat autoimmune diseases without the need for long term chemotherapy and to produce tolerance to therapeutic polypeptides such as interferon, IL-II or TNF. (44pp Dwg.No.0/13)

Abstract (Equivalent): EP 474691 B

Use of a **non-depleting** anti-CD4 monoaconal **antibody**, ie an **antibody** which causes depletion of fewer than 50% of CD4+ T-cells from the periphery as measured by changes in the peripheral blood lymphocyte numbers, for the manufacture of a medicament for the induction of a state of immunological tolerance to an antigen by a method which comprises administering said **non-depleting** anti-CD4 monoclonal **antibody** to a subject together with a **non-depleting** anti-**CD8** monoclonal **antibody**, ie an **antibody** which causes depletion of fewer than 50% of **CD8**+ T-cells from the periphery as measured by changes in the peripheral blood lymphocyte numbers, to induce an immunological tolerance permissive environment within said subject by means of said **antibodies** in the presence of said antigen.

(Dwg.0/11b

Abstract (Equivalent): US 5690933 A

Non depleting CD4 and **CD8** monoclonal **antibodies** are claimed for use in inducing tolerance to an antigen. The use of these **antibodies** and packs contg. them are also claimed. The prods. may also contain a depleting CD4 monoclonal **antibody** and/or a depleting **CD8** monoclonal **antibody**.

Single dose for a **human** is 1-400mg (esp. 3-30mg) of **antibody**. Admin. is parenteral e.g. intravenous.

USE/ADVANTAGE - For producing tolerance to foreign **immunoglobulins**, bone marrow and skin grafts. To treat autoimmune diseases without the need for long term chemotherapy and to produce tolerance to therapeutic polypeptides such as interferon, IL-II or TNF.

Mice given short courses of anti-**CD4** and anti-CD8 monoclonal **antibodies** became tolerant of allogeneic skin grafted at the same time. Tolerance could be obtained without T cell depletion across multiple minor antigen mismatches, both in native and primed animals, demonstrating that peripheral T cells could be tolerized, even if they had been previously activated. Where donor and recipient were incompatible across the whole major histocompatibility complex, specific tolerance could be achieved by using a combination of depleting following by **non-depleting antibodies** , where each alone was unsuccessful. Although mice clearly tolerated their original skin grafts, we observed in some strain combinations that a second fresh, but genotypically indentical graft, was slowly rejected. Such mice also possessed T cells which could proliferate to donor-type stimulator cells in vtiro. Whatever the mechanisms, we have demonstrated that operational transplantation tolerance can be achieved with simple, non-toxic **antibody** therapy. The introduction of comparable tolerance-inducing regimens in clinical organ transplantation could obviate the need for long-term immunosuppression and its unfortunate side effects.

We have investigated whether PBMC of HIV-1-seropositive subjects are as susceptible to in vitro infection by HIV-1 as are PBMC from seronegative

controls. Accordingly, stimulated PBMC from 19 HIV-1-infected subjects were inoculated with four different variants of HIV-1. None of these cultures produced either detectable quantitites of viral reverse transcriptase activity or p24 Ag following inoculation with HIV-1. In contrast, in five of six cases in which these PBMC were depleted of B cells by **antibody** plus complement prior to viral inoculation, the presence of viral reverse transcriptase and p24 Ag was detected. The presence of normal levels of **CD4** Ag at the surface of the **CD4**+ cells in these populations was established by flow cytometry. Analysis by an immunoblot assay revealed that anti-HIV **antibodies** were present in the sera obtained from these infected donors; in addition, 7 of 10 culture fluids derived from the **nondepleted** PBMC were shown to contain virus-neutralizing **antibodies** . Cultures which were depleted of B cells did not contain detectable levels of antiviral **antibodies** . Confirmation that the virus produced by the PBMC which had been depleted of B cells was of the strain used to infect the cultures, rather than that which initially caused patient infection, was provided on the basis of differential susceptibility to **antibody** neutralization. These results suggest that **antibodies** produced by B cells in cultures of PBMC from seropositive donors may restrict infection by HIV-1 of such cultures under laboratory conditions.

LANGUAGES: English
Our goal has been to develop ways to tolerize the mature immune system to any defined antigen. In this report we show that peripheral (post-thymic) T cells of mice can become tolerant to a range of antigens (human and rat **immunoglobulins** , and bone marrow and skin grafts that differ at multiple minor transplantation antigens). In the case of human gamma globulin (HGG), this required that the antigen be given under the cover of a short course of **non-depleting** anti-**CD4 antibody**, while for tolerance to skin and marrow grafts anti-CD8 **antibody** was also required. Tolerance to HGG could be reinforced by repeated injections of HGG, but was lost in the absence of any further exposure to antigen.

This reversal of tolerance with time was due to new T cells being exported from the thymus, as it was not observed in tolerized, adult thymectomized mice. In contrast, tolerance to marrow and skin grafts was permanent, presumably because the established grafts acted as a continuous source of antigen to reinforce the tolerant state. Tolerance could not be broken by the infusion of unprimed spleen cells and in one example (tolerance to Mls-1a) there was clear evidence that specific peripheral T cells were anergic. We propose that anergic cells may themselves participate in reinforcing the tolerant state by competing at sites of antigen presentation.

Document type: JOURNAL ARTICLE; REVIEW; REVIEW, TUTORIAL
Monoclonal **antibodies** to **CD4**, CD8 and CD11a can be used in vivo either to deplete or functionally block T cells to create a tolerance permissive environment. Short courses of **non-depleting CD4** and CD8 **antibodies** were used to induce tolerance separately in **CD4**+ and CD8+ T cells either to foreign **immunoglobulins**, bone marrow, or skin grafts. Tolerance was obtained to minor (non-MHC) transplantation antigens without T cell depletion even in actively sensitized mice, or to MHC plus minor antigens presented directly by skin grafts using combinations of depleting followed by blockading **CD4** and CD8 **antibodies** . In all cases, tolerance was specific to the antigen/tissue given under cover of **antibody** treatment, and in one example it could be shown that T cells directed to MLS-1a had been forced into an anergic state. This induction of tolerant, anergic T cells in the periphery is able to explain many of the features associated with tolerance, not only in the model systems using foreign antigens, but also in the normal regulation of anti-self responses and its failure in autoimmune diseases. It is our new found ability to use antigen under the cover of **antibody** treatment to accurately control the pattern of tolerant T cells in vivo that we refer to by using the term 'reprogramming'. We also describe the clinical treatment of one patient with an autoimmune vasculitis based on the ideas developed from the mouse models. (47 Refs.)

Abstract (Basic): WO 9015152 A

Non depleting CD4 and CD8 monoclonal **antibodies** are claimed for use in inducing tolerance to an antigen. The use of these **antibodies** and packs contg. them are also claimed. The prods. may also contain a depleting **CD4** monoclonal **antibody** and/or a depleting CD8 monoclonal **antibody**.

Single dose for a human is 1-400mg (esp. 3-30mg) of **antibody** . Admin. is parenteral e.g. intravenous.

USE/ADVANTAGE - For producing tolerance to foreign **immunoglobulins**, bone marrow and skin grafts. To treat autoimmune diseases without the need for long term chemotherapy and to produce tolerance to therapeutic polypeptides such as interferon, IL-II or TNF. (44pp Dwg.No.0/13)

Abstract (Equivalent): EP 474691 B

Use of a **non-depleting** anti-**CD4** monoaconal **antibody**, ie an **antibody** which causes depletion of fewer than 50% of **CD4**+ T-cells from the periphery as measured by changes in the peripheral blood lymphocyte numbers, for the manufacture

of a medicament for the induction of a state of immunological tolerance to an antigen by a method which comprises administering said **non-depleting** anti-**CD4** monoclonal **antibody** to a subject together with a **non-depleting** anti-CD8 monoclonal **antibody**, ie an **antibody** which causes depletion of fewer than 50% of CD8+ T-cells from the periphery as measured by changes in the peripheral blood lymphocyte numbers, to induce an immunological tolerance permissive environment within said subject by means of said **antibodies** in the presence of said antigen.

Depletion of **CD4**+ T lymphocytes with monoclonal **antibodies** (mAbs) has been shown to prolong allograft survival in mice. In this study, two rat anti-**CD4** mAbs, H129.19 and GK1.5, were administered either alone or in combination with cyclosporine (CsA) to recipients of MHC-mismatched (H-2k to H-2d) cultured fetal pancreas allografts to determine their effect on graft survival. When compared with control mice, splenic **CD4**+ cells of GK1.5-treated mice were depleted by > 95%, but in H129.19-treated mice no depletion of **CD4** + cells occurred. Instead, rat Ig was present on the surface of **CD4** + cells in H129.19-treated mice. Anti-**CD4** therapy with either H129.19 or GK1.5 prolonged fetal pancreas allograft survival to a similar extent, but did not lead to indefinitive survival. Blockade of the **CD4** antigen by the mAb H129.19 was as effective as the depletion of **CD4**+ cells by GK1.5 in prolonging allograft survival. Rejection of grafts by day 28 posttransplantation occurred in the absence of **CD4** + cells, as determined by both flow cytometric examination of spleen cells and immunoperoxidase staining of the graft site. CsA alone did not prolong graft survival, but its addition to either H129.19 or GK1.5 mAb treatment significantly increased the survival rate of grafts at 28 days compared

with mAb treatment alone. These results suggest that **CD4**+ cell depletion is not essential for effective anti-**CD4** mAb therapy-and, further, that CsA may have a direct inhibitory effect on CD8+ cells during allograft rejection.
